
Test De Reconocimiento De Caras De Benton !!INSTALL!!

to date, the majority of studies have used the quick test of face emotion identification, but this test is limited to the recognition of six basic emotions. in the present review, the studies that used the feest and the pofa have indicated that patients with schizophrenia have difficulties in processing facial emotional expressions in comparison to healthy controls. indices of executive function are often used to assess cognitive deficits in schizophrenia. although several studies have provided evidence that deficits in fer are correlated with the severity of these deficits, this correlation is not consistent across studies. recently, it has been suggested that the application of tools such as the set (sorting test; stone et al., 1990) might be useful to differentiate between patients with cognitive and psychosocial deficits and those with deficits primarily related to the fer. in addition, the use of perceptual variables to explain deficits in fer has been extensively used. frings et al. (2011) found that visual impairment or lack of experience with facial expressions could be related to the difficulties of patients with schizophrenia in interpreting emotional expressions. the present study sought to evaluate the relationship between fer and mental health status. it is recommended that the fer be used to evaluate emotional facial expressions in individuals with schizophrenia, as it is a reliable and valid test that can be used in different populations and with different populations. because it is easy to administer, it is recommended that it be used in clinical practice and research for diagnostic and prognostic purposes.
